

What is Artificial Intelligence?

Simply put, it is a field of computing which covers building systems that can perform tasks which normally human intelligence takes care of, such as classification, mathematical computation, prediction, and what not.

It is not actually one algorithm, it is a whole domain spanning multiple algorithms, architectures, and approaches.

In classical programming, we would have certain rules, or syntax, and once the data was applied to those particular rules, we would get a desired output.

In machine learning, a field of artificial intelligence, we have a bunch of data, and we know what output we desire from the data, and we train the model to give us the output from the data, and then make use of the model to give outputs for new data.
